*In this study we have investigated fifteen novel lasing media of organic compounds, which are series of organic molecules with different substitutes, capable of producing laser emission in the region from 600 to 680 nm if pumped by radiation of a XeCl–laser. Ten lasing characteristics of each compound are compared to those of a rhodamine 6G solution. It is shown that although the lasing efficiency (or the efficiency of the XeCl–laser emission conversion) of these compounds is lower they provide longer lifetimes of lasing media compared to that of rhodamine 6G. The relation of an active medium lifetime to light absorption by the photodissociation products in the spectral regions of generation and pumping is analyzed.*

Stable frequency conversion of excimer laser emissions into emissions of the visible and IR regions is still a topical applied problem. In this connection we have studied lasing properties of some novel organic compounds (see Fig. 1) soluble in ethanol. Excitation of these lasing media was performed with a XeCl–laser radiation at the 308 nm wavelength and 30–70 mW mean power at a repetition rate of 2 Hz. The technique of measuring parameters of laser emission we used in our study had been described earlier in Ref. 1. Table I presents the values of absorption coefficients  $K_{\lambda p}$  of lasing media at the wavelength of pumping radiation, interval of the emission wavelengths  $\Delta\lambda_g$ ,

wavelength of the emission maximum  $\lambda_{le}^{max}$ , the value of the initial efficiency  $\eta_0 = P_{le}/P_p$ , where  $P_{le}$  is the mean power of laser emission and  $P_p$  is the mean power of pumping radiation. The values  $P_{80}$  and  $P_{50}$  are the lasing lifetimes defined as the energy pumped into 1 cm<sup>3</sup> of a lasing medium during the time interval from the beginning of lasing till the moment when the starting efficiency of lasing  $\eta_0$  decreases by 20 or 50 percent, respectively. Normally, the decreases of  $\eta_0$  is assumed to be due to photochemical transformations.

TABLE I. Lasing characteristics of the compounds under study.

\* Structures of the designated compounds are presented in Fig. 1.

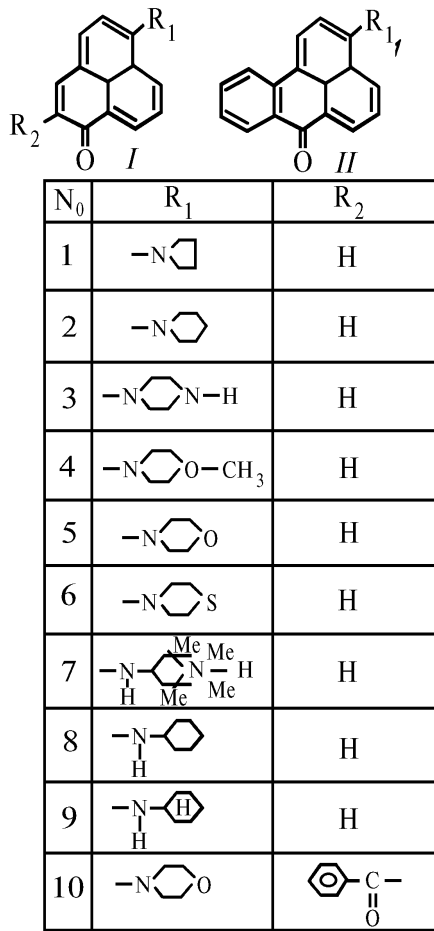

FIG. 1. Structures of the molecules under study.

Based on the experimental data we calculated the molecular yield of photochemical transformations

$$\varphi_{ph} = \frac{(1 - c/c_0) c_0}{E_t} = \frac{\text{the number of dissociated molecules}}{\text{the number of absorbed photons}},$$

FIG. 2. Absorption spectra of the compounds II (6) – curves 1 and 2; and II (4) – curves 3 and 4; spectra 1 and 3 were observed prior to lasing while the spectra 2 and 4 after its termination. The thickness of the layer was 0.025 cm (curves 1–4) and 1 cm (curves 1'–4').

where  $c_0$  and  $c$  are the initial and final values of the concentration of molecules, respectively,  $E_t$  is the total (in number of photons) energy pumped into the lasing solution during the time when the concentration of molecules decreased from  $c_0$  down to  $c$ . In addition we calculated the lasing yield of the photochemical transformations

$$P_{ph} = \frac{1 - \eta/\eta_0}{E_t},$$

where  $E_t$  is the total energy pumped into 1  $\text{cm}^3$  of the lasing solution during the time when the lasing efficiency decreases from the initial value  $\eta_0$  down to  $\eta$ . From the absorption spectra (see Fig. 2) we determined the increase of the optical density of the lasing solution in the spectral region of lasing emission normalized by the number of absorbed photons  $\Delta D_{le} / E_t$ .

Comparison of the lasing properties of these media shows that the efficiency of an excimer laser radiation conversion is 2–5 times lower than that of a rhodamine 6G solution. At the same time it is obvious that the lifetime of the most efficient media is about 10 times as long as that of rhodamine 6G.

In our experiments we have obtained that addition of a fused ring shifts the laser emission spectrum towards longer wavelengths by about 50 nm and makes the lasing lifetime 3–5 times longer compared to that of similar but 3–ring compounds (see Fig. 1 and Table I). The molecule with a substitute of an alkylated cyclic aminogroup has the longest lifetime. At the same time the change of oxygen for sulphur in a morfoline substitute results only in a small shift of the laser emission spectrum towards shorter wavelengths ( $\approx 5$  nm) while sharply decreases the lasing efficiency and the lifetime.

The correlation between the lifetime and the light absorption by photodissociation products at  $\lambda_{lasing}$  is higher than that between the lifetime and the quantum yield of photochemical transformations  $\varphi_{ph}$ , though the relation is not unique. The latter means that the lifetime is determined by both these processes.

In this study we have also revealed that the rate of the lasing efficiency  $P_{ph}$  fall off occurring during the photochemical transformations for all media, is higher than the rate of the corresponding fall off of the number

density of lasing molecules  $\varphi_{ph} = \frac{(1 - c/c_0) c_0}{E_t}$ . This

means that the light absorption by the products of photochemical dissociation at the wavelengths  $\lambda_{le}$  and  $\lambda_p$  additionally affects the lifetime of the lasing media. In the case of media with higher photochemical durability the absorption of light at  $\lambda_p$  decreases during the lasing process while in the case of media with lower photochemical stability this absorption either increases or keeps unchanged.

Light absorption by the products of photochemical dissociation at the wavelengths of laser emission  $\lambda_{le}$  is the weakest in the case of media with the longest lifetime. By

the way, the shortest lifetime has the most unstable dye, though its light absorption at  $\lambda_{le}$  is not the strongest one (see the table). However, the data presented in Fig. 2 show that in this case the longwave absorption band of the photochemical dissociation products is most intensive.

In addition to certain practical recommendations which can be drawn from the experimental results obtained in this study of lasing properties of the above substances such investigations could be useful for seeking for regularities in dissipation of the pump energy in complex organic molecules using, for example, methods of quantum chemistry. Such studies could facilitate our understanding of the role of a substitute in related series of compounds in physics and photochemistry of molecules.
